predators of the ocean floor

Anglerfish are named for the long filament that extends from a fin on the top of their head out in front of their bodies. It is an extension of their spine and acts as a "fishing rod." The tip has bioluminescent bacteria in it, which the fish uses as bait. Since the ocean is completely dark where they live, other animals and fish are attracted to their light, but when they get too close, the anglerfish eats them with its large mouth. Its mouth, jaw, and belly are so flexible they have even been known to swallow prey twice their size. They developed this ability because there are not many fish that live deep in the ocean, and they do not always get to eat every day.

 Watch this videos of a pink harry frogfish hunting.

 Describe how anglerfish hunt for their prey.
